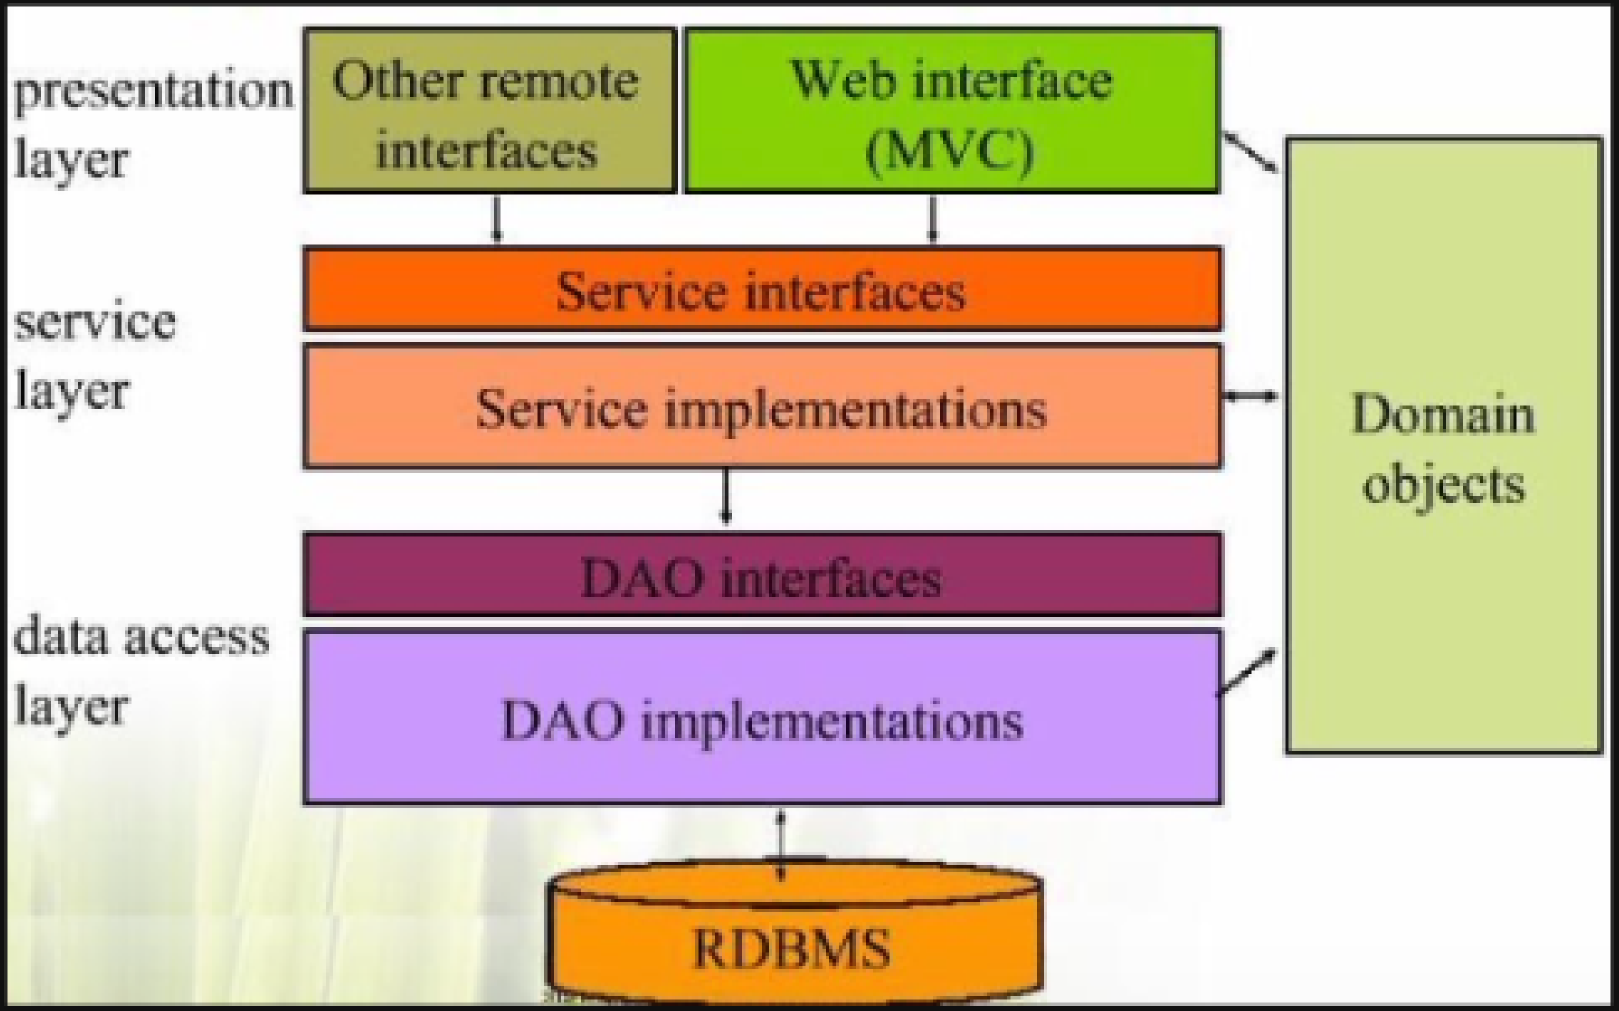
Three-Tier Architectures

→ **Serverless Architecture**

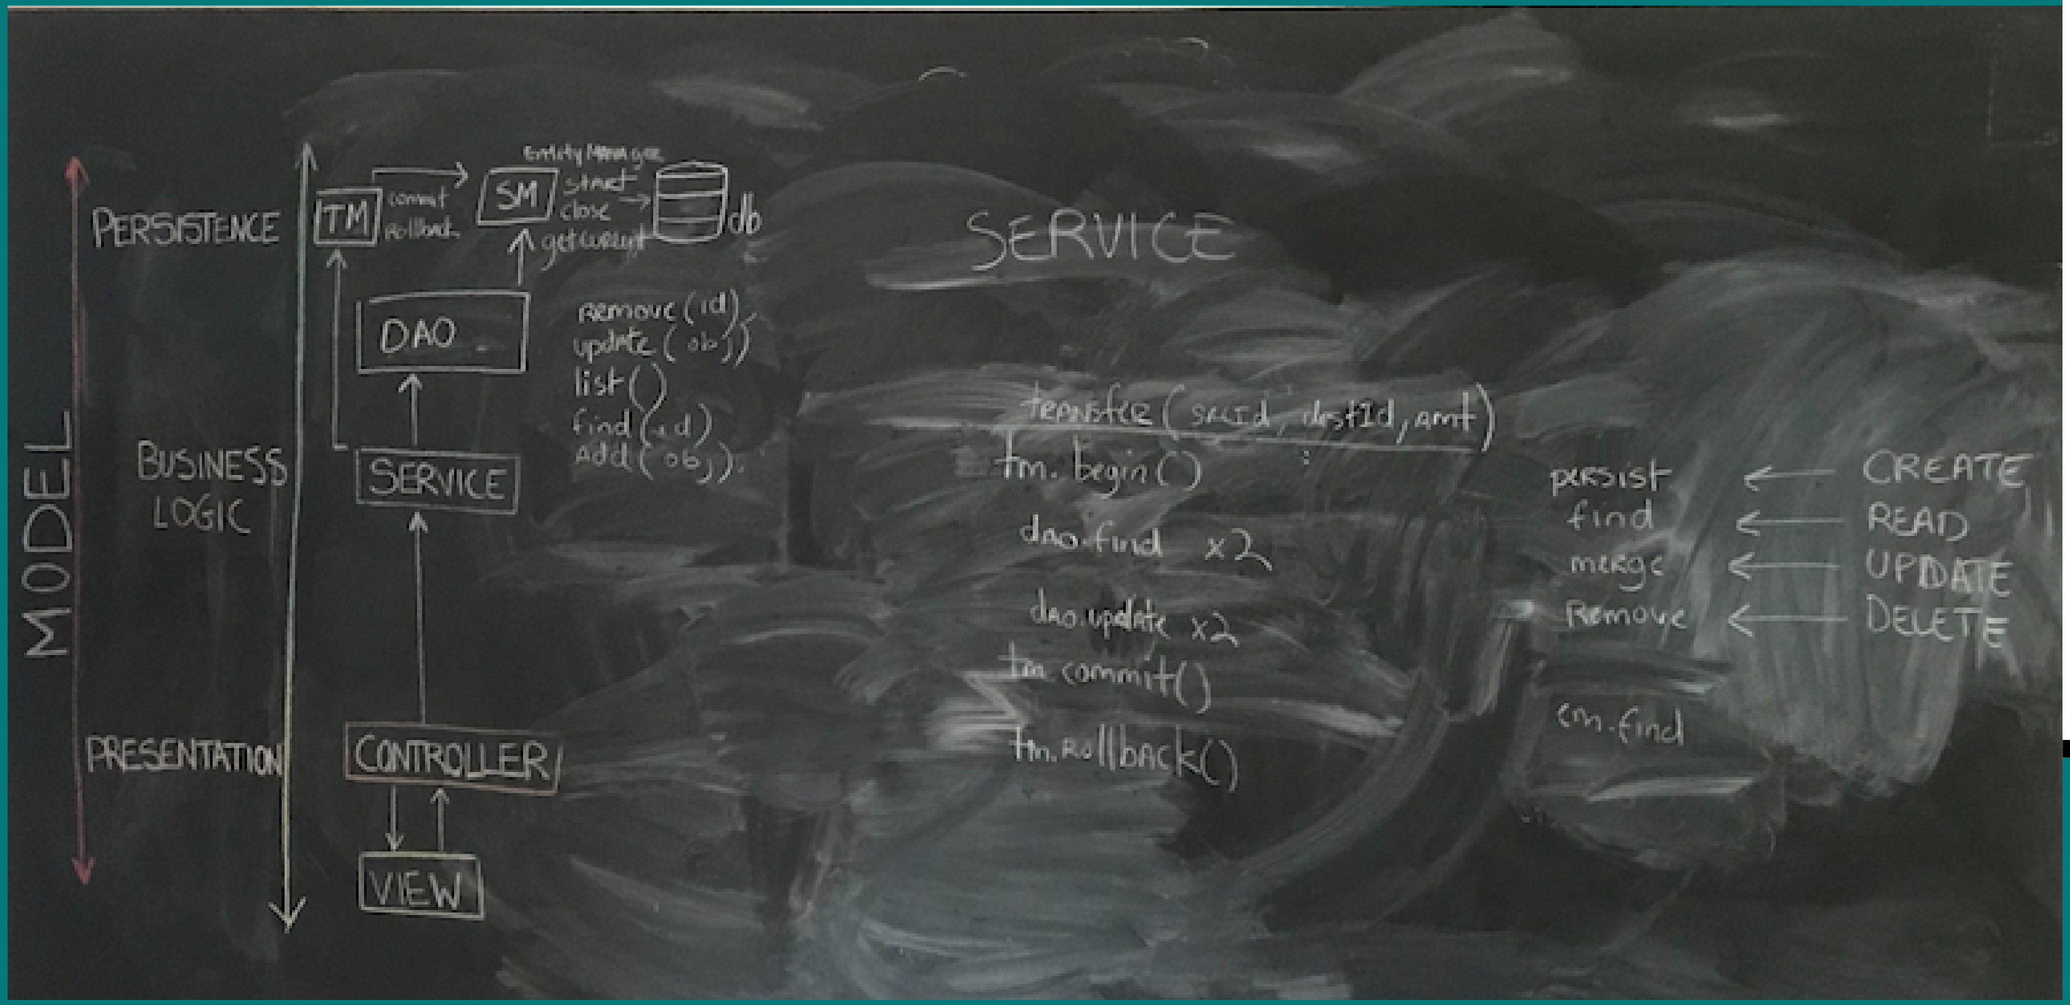
Application Layering

Layering is one of the most common techniques used to break apart a complicated software system

- A single layer can be understood as a coherent whole without knowing much about the other layers
- Layers can be substituted with alternative implementations of the same basic services
- Dependencies between layers can be minimized, reducing the overall coupling in the system



Data Access Object



DAO is an important design pattern used at the persistence layer

- Separates low level data access from high level business services
- Handles data access and manipulation from the persistence storage (db, ldap, file system, etc.)
- Decouples the persistent storage implementation from the rest of the application

Ex.Implement the Generic Dao on the JavaBank application

```
public class CustomerDAO {

JpaSessionManager jpaSessionManager;

    public Customer find(Integer id){
        EntityManager em = jpaSessionManager.getCurrentSession();
        return em.find(Customer.class, id);

    }

    public void add( Customer customer){
        EntityManager em = jpaSessionManager.getCurrentSession();
        em.persist(customer);
    }
```

Ex.Implement the Generic Dao on the JavaBank application

```
public class JpaCustomerService implements CustomerService {

  private CustomerDAO dao;
  private JpaTransactionManager tm;

  public Customer get(Integer id) {

        tm.beginRead();
        Customer customer = dao.find(id);
        tm.commit();
        return customer;
    }

  public void add(Customer customer){
        tm.beginWrite();
        dao.add(customer);
        tm.commit();
    }

    }
```
